Developing firmware involves initializing UART, sending, and receiving data through it, and handling data processing.

UART Initialization

Set the UART module for your desired baud rate, data bits, stop bits, and parity. Example for PIC16 microcontroller in C:

```
```\n\n// Initialize UART\n\nvoid UART_Init(long baud_rate) {\n\n// Configure UART pins\n\nTRISCbits.TRISC6 = 0; // TX pin as output\n\nTRISCbits.TRISC7 = 1; // RX pin as input\n\n// Calculate SPBRG value based on baud rate
```

```
// For 16MHz clock and high-speed mode

unsigned int spbrg_value = (_XTAL_FREQ / (4 baud_rate)) - 1;

TXSTA = 0x24; // TX enable, high speed

RCSTA = 0x90; // Enable serial port, enable receiver

BAUDCTLbits.BRG16 = 1; // 16-bit Baud Rate Generator

SPBRGH = (spbrg_value >> 8);

SPBRG = spbrg_value & 0xFF;

}

...

```

## **Sending Data**

- Use a function to send characters or strings over UART.
- Implement blocking or interrupt-driven transmission depending on your application.

void UART_Write(char data) {

while(!PIR1bits.TXIF); // Wait until TX buffer is ready

TXREG = data; // Transmit data

}

```

```
void UART_Write_String(const char str) {  
  
while(str) {

Advanced Viva Questions and Analytical Topics

Q10. Discuss the importance of timers in microcontroller applications.

Answer:

Timers are crucial peripherals that generate precise delays, measure time intervals, and generate PWM signals. They facilitate:

- Event scheduling: Trigger actions after specific intervals.
- Pulse Width Modulation (PWM): Control motor speed, LED brightness.
- Frequency generation: For sound generation or clock signals.
- Real-time clock functions: Keep track of time in embedded systems.

Timers enhance system functionality, accuracy, and efficiency, making them indispensable in complex applications.

Q11. Explain the concept of watchdog timer and its necessity.

Answer:

A watchdog timer is a hardware timer that resets the microcontroller if the software fails to periodically refresh (or 'kick') it. Its purpose is to:

- Prevent system hang-ups: Ensures system recovery from faults.
- Enhance reliability: Critical in safety-critical applications like medical devices or automotive systems.
- Implementation: Usually configured to reset the system if not cleared within a specified timeout period.

The watchdog timer acts as a fail-safe mechanism, maintaining system stability.

Question What is a microcontroller and how does it differ from a microprocessor? A microcontroller is a compact integrated circuit that includes a processor, memory, and I/O peripherals on a single chip, designed for embedded applications. Unlike a microprocessor, which primarily contains only the CPU and requires external components for full operation, a microcontroller is self-contained and optimized for specific control tasks. Explain the concept of a timer in a microcontroller and its applications. A timer in a microcontroller is a hardware peripheral used to measure time intervals or generate precise delays. It can be used for event counting, generating PWM signals, or creating time delays in applications such as motor control, real-time clocks, and communication protocols. What are the different types of memory available in a microcontroller? Microcontrollers typically have several types of memory including Flash (program memory), RAM (data memory), EEPROM (electrically erasable programmable read-only memory), and sometimes ROM. Flash memory stores the program code, RAM is used for temporary data during execution, and EEPROM is used for non-volatile data storage. Describe the role of the program counter in a microcontroller. The program counter (PC) is a register that holds the memory address of the next instruction to be executed. It automatically increments after each instruction fetch, ensuring sequential execution of instructions unless a jump or branch alters its value. What are interrupt vectors and how are they used in microcontroller programming? Interrupt vectors are specific memory addresses that contain the starting addresses of interrupt service routines (ISRs). When an interrupt occurs, the microcontroller jumps to the corresponding vector to execute the ISR, allowing the system to respond quickly to external or internal events. Explain the difference between polling and interrupt-driven data transfer. Polling involves the CPU actively checking the status of a device at regular intervals to see if it needs attention, which can be inefficient. Interrupt-driven transfer allows the device to notify the CPU via an interrupt when it requires service, enabling more efficient CPU utilization and responsiveness. What are the typical I/O interfaces available in microcontrollers? Microcontrollers generally provide digital I/O pins, analog input pins (ADC), communication interfaces like UART, SPI, I2C, and PWM outputs for controlling external devices such as motors, sensors, and displays. How does a watchdog timer function in a microcontroller system? A watchdog timer is a hardware timer that resets the microcontroller if the system becomes unresponsive or enters an infinite loop. The software must periodically reset or 'kick' the watchdog to prevent a system reset, thereby enhancing system reliability.
